

# Divide-and-Conquer Colouring for Restricted Inputs

## 1 Divide-and-conquer algorithms

Many useful algorithms are recursive, i.e. call themselves recursively to deal with subproblems

At each level of recursion:

- **Divide** the problem into a number of subproblems
- **Conquer** the subproblems by solving them: recursively, or straightforward if the subproblem sizes are small enough
- **Combine** the solutions for the subproblems into a solution for the original problem

## 2 Problem Definition

### Definition: Colouring

An assignment of colours to the vertices of a graph such that no two adjacent vertices get the same colour

### Definition: k-colouring

A colouring using at most  $k$  colours

### Definition: Chromatic number $\chi_G$

The smallest integer  $k$  for which  $G$  has a  $k$ -colouring

The task of given a graph  $G$  determining  $\chi_G$  is an NP hard problem

## 3 How to deal with NP-hardness

This can be done in several ways. For example:

- Heuristics
- Approximation algorithms
- Exact algorithms
- Parametrized algorithms
- Algorithms with restricted inputs

We focus on the last approach. That is, we exploit the structure of the input with an aim to develop faster algorithms. Justification

1. In practice problem inputs may exhibit structure
2. By focussing on the input structure we understand better what structure makes a problem computationally hard

## 4 Definition

Let  $G_1$  and  $G_2$  be two vertex-disjoint graphs

The **disjoint union**  $G_1 + G_2$  of  $G_1$  and  $G_2$  is the graph with the vertex set and edge set of the union of them. There is no overlap between  $G_1$  and  $G_2$

The **join**  $G_1 \times G_2$  is the graph with vertex set  $V(G_1) \cup V(G_2)$  and edge set  $E(G_1) \cup E(G_2) \cup E^*$ , where  $E^*$  is the set of all edges between vertices of  $G_1$  and vertices of  $G_2$ . Adding all possible edges between the graphs

A graph  $G$  is a **cograph** iff  $G$  can be created by the following rules

- The 1-vertex graph  $K_1$  is a cograph
- If  $G_1$  and  $G_2$  are cographs, then so is  $G_1 + G_2$
- If  $G_1$  and  $G_2$  are cographs, then so is  $G_1 \times G_2$

### Important: Cographs

$P_4$  is the smallest graph that is not a cograph

## 5 Alternate definition

Let  $P_4$  denote the path on 4 vertices

A graph  $G$  contains  $P_4$  as an induced subgraph if  $G$  can be modified to  $P_4$  via vertex deletions

If not, then  $G$  is said to be  $P_4$ -free

It is known that a graph is a cograph iff it is  $P_4$ -free

## 6 Definition of a cotree

A cotree  $T_G$  of a cograph  $G$  is the unique decomposition tree satisfying

1. Its root  $r$  corresponds to the graph  $G_r = G$
2. Every leaf  $x$  of  $T$  corresponds to exactly one vertex of  $G$ , and vice versa
3. Every internal node  $x$  of  $T$  has at least two children, is either labelled  $+$  or  $\times$ , and corresponds to an induced subgraph  $G_x$  of  $G$  defined as follows:
  - If  $x$  is a  $+$ -node, then  $G_x$  is the disjoint union of all graphs  $G_y$ , where  $y$  is a child of  $x$
  - If  $x$  is a  $\times$ -node, then  $G_x$  is the join of all graphs  $G_y$  where  $y$  is a child of  $x$
4. Labels of internal nodes on the (unique) path from any leaf to  $r$  alternate between  $+$  and  $\times$

This tree shows the composition of a cograph, each internal node is an operation and each leaf is a vertex of the graph

## 7 Solving colouring for cographs

Let  $G$  be a cograph on  $n$  vertices and  $m$  edges

We construct its cotree  $T_G$ . This can be done in  $O(n + m)$  time

We follow a bottom up approach: only process node  $x$  after first processing its children.

Leaves: Each leaf corresponds to a single vertex of  $G$ . The chromatic number of a single-vertex graph is 1

Union-nodes: Let  $x$  be a  $+$ -node. Then  $\chi_{G_x}$  is the maximum number of the chromatic numbers of the graphs  $G_y$ , where  $y$  is a child of  $x$

Join-nodes. Let  $y$  be a  $\times$ -node. Then  $\chi_{G_x}$  is the sum of the chromatic numbers of the graphs  $G_y$ , where  $y$  is a child of  $x$

In this way the last node we process is node  $r$ , which corresponds to the graph  $G_r = G$

As the number of nodes of  $T$  is  $O(n)$  and we used linear time per node, the total running time is polynomial
